

Environnement

<code>mkdir project_name && cd \$_</code>	Create project folder and navigate to it
<code>python -m venv env_name</code>	Create venv for the project
<code>source env_name/bin/activate</code>	Activate environnement (Replace "bin" by "Scripts" in Windows)
<code>pip install django</code>	Install Django (and others dependencies if needed)
<code>pip freeze > requirements.txt</code>	Create requirements file
<code>pip install -r requirements.txt</code>	Install all required files based on your pip freeze command
<code>git init</code>	Version control initialisation, be sure to create appropriate gitignore

Create project

<code>django-admin startproject mysite</code> (or I like to call it config)	This will create a mysite directory in your current directory the manage.py file
<code>python manage.py runserver</code>	You can check that everything went fine

Database Setup

Open up <code>mysite/settings.py</code>	It's a normal Python module with module-level variables representing Django settings.
<code>ENGINE = 'django.db.backends.sqlite3', 'django.db.backends.postgresql', 'django.db.backends.mysql', or 'django.db.backends.oracle'</code>	If you wish to use another database, install the appropriate database bindings and change the following keys in the DATABASES 'default' item to match your database connection settings
<code>NAME</code> - The name of your database. If you're using SQLite, the database will be a file on your computer; in that case, NAME should be the full absolute path, including filename, of that file.	The default value, <code>BASE_DIR / 'db.sqlite3'</code> , will store the file in your project directory.
If you are not using SQLite as your database, additional settings such as <code>USER</code> , <code>PASSWORD</code> , and <code>HOST</code> must be added.	For more details, see the reference documentation for DATABASES .

Creating an app

<code>python manage.py startapp app_name</code>	Create an app_name directory and all default file/folder inside
<code>INSTALLED_APPS = ['app_name', ...]</code>	Apps are "pluggable", that will "plug in" the app into the project

Creating an app (cont)

```
urlpatterns = [
    path('app_name/', include('app_name.urls')),
    path('admin/', admin.site.urls),
]
```

Into urls.py from project folder, include app urls to project

Creating models

```
class ModelName(models.Model):
    title = models.CharField(max_length=100)

    def __str__(self):
        return self.title
```

Create your class in the app_name/models.py file

Create your [fields](#)

It's important to add `__str__()` methods to your models, because objects' representations are used throughout Django's automatically-generated admin.

Database editing

```
python manage.py makemigrations app_name
```

By running makemigrations, you're telling Django that you've made some changes to your models

```
python manage.py sqlmigrate #identifier
```

See what SQL that migration would run.

```
python manage.py check
```

This checks for any problems in your project without making migrations

```
python manage.py migrate
```

Create those model tables in your database

```
python manage.py shell
```

Hop into the interactive Python shell and play around with the free API Django gives you

Administration

```
python manage.py createsuperuser
```

Create a user who can login to the admin site

```
admin.site.register(ModelName)
```

Into app_name/admin.py, add the model to administration site

<http://127.0.0.1:8000/admin/>

Open a web browser and go to "/admin/" on your local domain

Management

```
mkdir app_name/management app_name/management/commands &&
cd $_
```

Create required folders

```
touch your_command_name.py
```

Create a python file with your command name

(cont)

```
from django.core.management.base import BaseCommand
#import anything else you need to work with (models?)
```

Edit your new python file, start with import

```
class Command(BaseCommand):
    help = "This message will be shown with the --help option after your command"
```

Create the Command class that will handle your command

```
def handle(self, args, *kwargs):
    # Work the command is supposed to do
```

```
python manage.py my_custom_command
```

And this is how you execute your custom command

Django lets you create your custom CLI commands

Write your first view

```
from django.http import HttpResponse
def index(request):
    return HttpResponse("Hello, world. You're at the index.")
```

Open the file `app_name/views.py` and put the following Python code in it.
This is the simplest view possible.

```
from django.urls import path
from . import views
```

In the `app_name/urls.py` file include the following code.

```
app_name = "app_name"
urlpatterns = [
    path('', views.index, name='index'),
]
```

View with argument

```
def detail(request, question_id):
    return HttpResponse(f"You're looking at question {question_id}")
```

Exemple of view with an argument

```
urlpatterns = [
    path('<int:question_id>/', views.detail, name='detail'),
    ...
```

See how we pass argument in path

```
{% url 'app_name:view_name' question_id %}
```

We can pass attribute from template this way

View with Template

<code>app_name/ templates /app_name /index.html</code>	This is the folder path to follow for template
<code>context = {'key': value}</code>	Pass values from view to template
<code>return render (request, 'app_name /index.html', context)</code>	Example of use of render shortcut
<code>{% Code %}</code> <code>{{ Variable from view's context dict }}</code> <code> </code> <code><title>Page Title< /title></code>	Edit template with those. Full list here you can put this on top of your html template to define page title

Add some static files

<code>'django.contrib.staticfiles'</code>	Be sure to have this in your INSTALLED_APPS
<code>STATIC_URL = 'static/'</code>	The given examples are for this config
<code>mkdir app_name/ static app_name/ static /app_name</code>	Create static folder associated with your app
<code>{% load static %}</code>	Put this on top of your template
<code><link rel="stylesheet" type="text/css" href="{% static 'app_name /style.css' %}"></code>	Example of use of static.

Raising 404

<code>raise Http404("Question does not exist")</code>	in a try / except statement
<code>question = get_object_or_404(Question, pk=question_id)</code>	A shortcut

Forms

<code>app_name/ forms.py</code>	Create your form classes here
<code>from django import forms</code>	Import django's forms module
<code>from .models import YourModel</code>	import models you need to work with
<code>class ExampleForm(forms.Form):</code> <code>example_field = forms.CharField(label='Example label', max_length=100)</code>	For very simple forms, we can use simple Form class
<code>class ExampleForm(forms.ModelForm):</code> <code>class meta:</code> <code>model = model_name</code> <code>fields = ["fields"]</code> <code>labels = {"text": "label_text"}</code> <code>widget = {"text": forms.widgets.Textarea}</code>	A ModelForm maps a model class's fields to HTML form <input> elements via a Form. Widget is optional. Use it to override default widget
<code>TextInput, EmailInput, PasswordInput, DateInput, Textarea</code>	Most common widget list
<code>if request.method != "POST":</code> <code>form = ExampleForm()</code>	Create a blank form if no data submitted

Forms (cont)

```
form = ExampleForm(data=request.POST)
```

The form object contains the information submitted by the user

```
if form.isvalid():
    {% csrf_token %}
    form.save()
```

Form validation. Always use redirect function
Template tag to prevent "cross-site request forgery" attack

```
return redirect("app_name:view_name", argument=
argument)
```

Render Form In Template

```
{{ form.as_p }}
```

The most simple way to render the form, but usually it's ugly

```
{{ field|placeholder:field_label }}
{{ form.user_name|placeholder:"Your name
here" }}
```

The | is a filter, and here for placeholder, it's a custom one. See next section to see how to create it

```
{% for field in form %}
    {{form.username}}
```

You can extract each field with a for loop.
Or by explicitly specifying the field

Custom template tags and filters

```
app_name \templates \__init__.py
```

Create this folder and this file. Leave it blank

```
app_name \templates \filter_name.py
```

Create a python file with the name of the filter

```
{% load filter_name %}
```

Add this on top of your template

```
from django import template
```

To be a valid tag library, the module must contain a module-level variable named register that is a template.Library instance

```
register = template.Library()
```

```
@register.filter(name='cut')
```

Here is an example of filter definition.

```
def cut(value, arg):
```

See the decorator? It registers your filter with your Library instance.

```
    """ Removes all values of arg from the given string """
```

You need to restart server for this to take effects

```
    return value.replace(arg, '')
```

Setting Up User Accounts

Create a "users" app

Don't forget to add app to settings.py and i from users.

```
app_name = "users"
urlpatterns[
    # include default auth urls.
    path("", include("django.contrib.auth.urls"))
]
```

Inside app_name/urls.py (create it if inexistent) this code includes some default authentication Django has defined.

```
{% if form.error %}
    <p>Your username and password didn't match</p>
{% endif %}
<form method="post" action="{% url 'users :login' %}">
    {% csrf_token %}
    {{ form.as_p }}

    <button name="submit">Log in</button>
    <input type="hidden" name="next" value="{% url 'app_name :index' %}" />
</form>
```

Basic login.html template
Save it at save template as users/templates/registration/login.html
We can access to it by using
a

```
{% if user.is_authenticated %}
```

Check if user is logged in

```
{% url "users: logout" %}
```

Link to logout page, and log out the user
save template as users/templates/registration/logout.html

```
path("register/", views.register, name="register"),
```

Inside app_name/urls.py, add path to register

```
from django.shortcuts import render, redirect
from django.contrib.auth import login
from django.contrib.auth import UserCreationForm
```

We write our own register() view inside use
For that we use UserCreationForm, a Django model.

```
def register(request):
    if request.method != "POST":
        form = UserCreationForm()
    else:
        form = UserCreationForm(data=request.POST)

    if form.is_valid():
        new_user = form.save()
        login(request, new_user)
        return redirect("app_name:index")

    context = {"form": form}
    return render(request, "registration/register.html", context)
```

If method is not post, we render a blank form
Else, is the form pass the validity check, then
We just have to create a registration.html template folder as the login and logged_out

Allow Users to Own Their Data

```
...
from django.contrib.auth.decorators import login_required
...

```

Restrict access with `@login_required` decorator

If user is not logged in, they will be redirected to the login page
To make this work, you need to modify `settings.py` so Django knows where to find the login page

Add the following at the very end

```
@login_required
def my_view(request)
    ...

```

My settings

`LOGIN_URL = "/users/login/"`

```
...
from django.contrib.auth.models import User
...
owner = models.ForeignKey(User, on_delete=models.CASCADE)

```

Add this field to your models to connect data to certain users

When migrating, you will be prompted to select a default value

```
user_data = ExampleModel.objects.filter(owner=request.user)

```

Use this kind of code in your views to filter data of a specific user

`request.user` only exists when user is logged in

```
...
from django.http import Http404
...

```

Make sure the data belongs to the current user

```
...
if example_data.owner != request.user:
    raise Http404

```

If not the case, we raise a 404

```
new_data = form.save(commit=False)
new_data.owner = request.user
new_data.save()

```

Don't forget to associate user to your data in corresponding views

The "commit=False" attribute lets us do that

Paginator

```
from django.core.paginator import Paginator

```

In `app_name/views.py`, import `Paginator`

```
example_list = Example.objects.all()

```

In your class view, Get a list of data

```
paginator = Paginator(example_list, 5) # Show 5 items per page.

```

Set appropriate pagination

```
page_number = request.GET.get('page')

```

Get actual page number

```
page_obj = paginator.get_page(page_number)

```

Create your Page Object, and put it in the context

```
{% for item in page_obj %}

```

The Page Object acts now like your list of data

Paginator (cont)

```
<div class="pagination">
  <span class="step-links">
    {% if page_obj.has_previous %}
      <a href="?page=1">&laquo; first</a>
      <a href="?page={{ page_obj.previous_page_number }}">previous</a>
    {% endif %}
    <span class="current"> Page {{ page_obj.number }} of {{ page_obj.paginator.num_pages }}. </span>
    {% if page_obj.has_next %}
      <a href="?page={{ page_obj.next_page_number }}">next</a>
      <a href="?page={{ page_obj.paginator.num_pages }}">last &rquo;</a>
    {% endif %}
  </span>
</div>
```

An
exemp
of wha
to put
the
bottom
of your
page
to
naviga
throug
Page
Object

Deploy to Heroku

<https://heroku.com>

Make a Heroku account

<https://devcenter.heroku.com/articles/heroku-cli/>

Install Heroku CLI

```
pip install psycog2
pip install django -heroku
pip install gunicorn
```

install these packages

```
pip freeze > requirements.txt
```

update requirements.txt

```
# Heroku settings.
import django_heroku
django_heroku.settings(locals(), staticfiles= False)

if os.getenv('DEBUG') == "TRUE":
    DEBUG = True
elif os.getenv('DEBUG') == "FALSE":
    DEBUG = False
```

At the very end of settings.py, make an Heroku settings section
import django_heroku and tell django to apply django heroku settings
The staticfiles to false is not a viable option in production, check
whitenoise for that IMO
